AGU Fall 2003

# Polar Convection

- The SAPS electric field produces a westward plasma flow at subauroral latitudes
- Some plasma travels through dayside cusp into polar regions where it becomes entrained in the polar convection and carried over the pole

# Outline

---

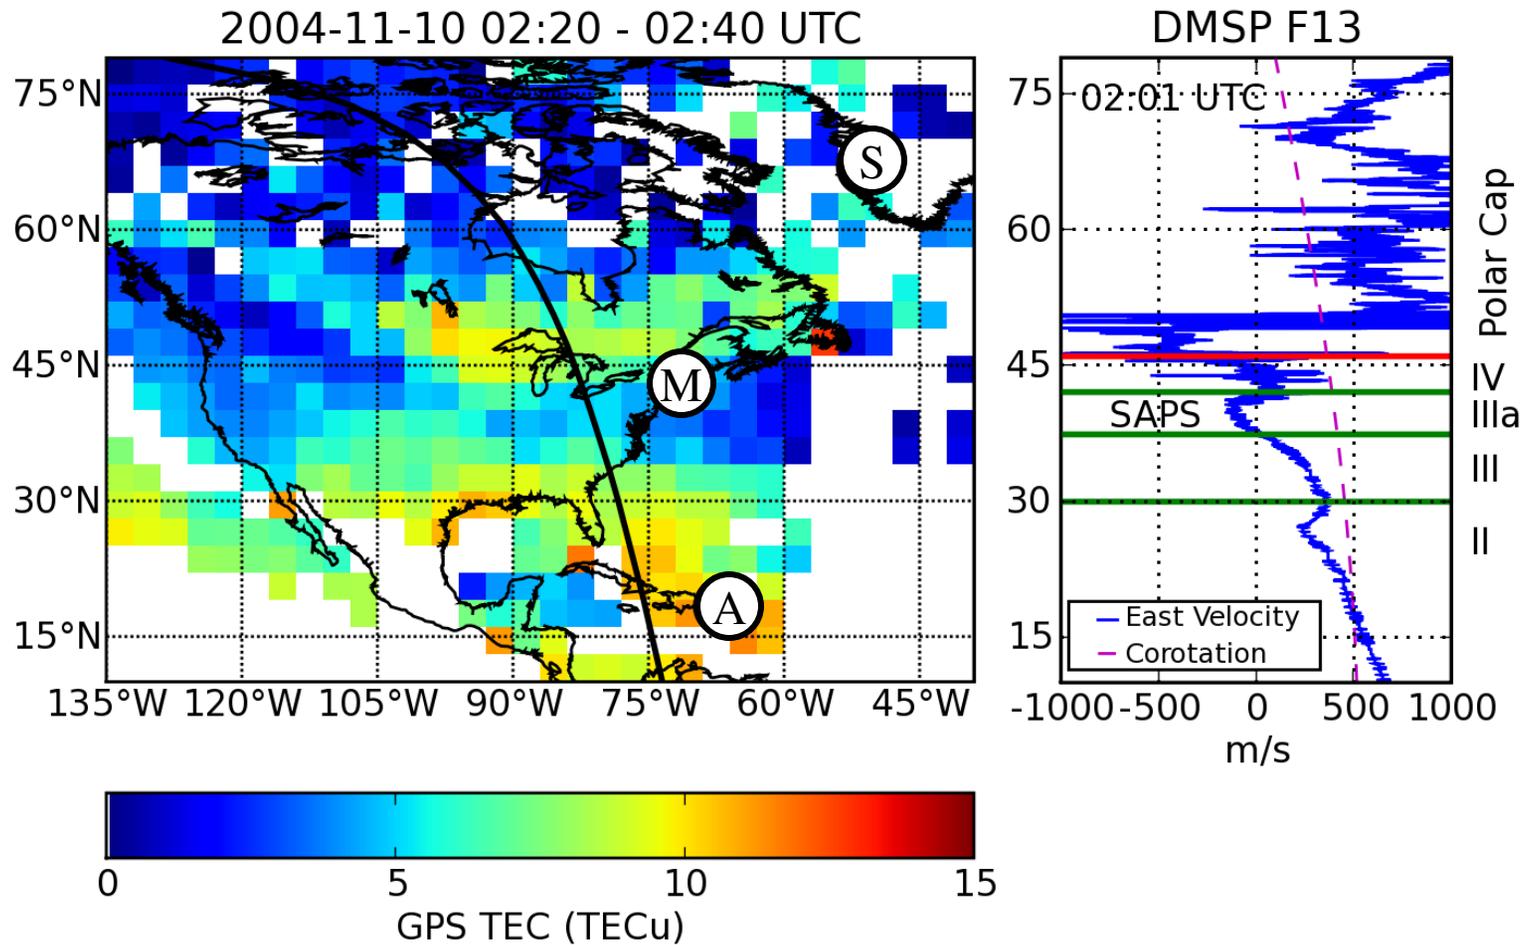

- Geomagnetic Conditions
- Context and Boundaries
- Auroral Stations: Millstone Hill and Sondrestrom
- Millstone Hill Dusk Sector Dynamics
- Millstone Hill, Arecibo Neutral Wind Surges / Dynamios
- TIMEGCM
- Summary

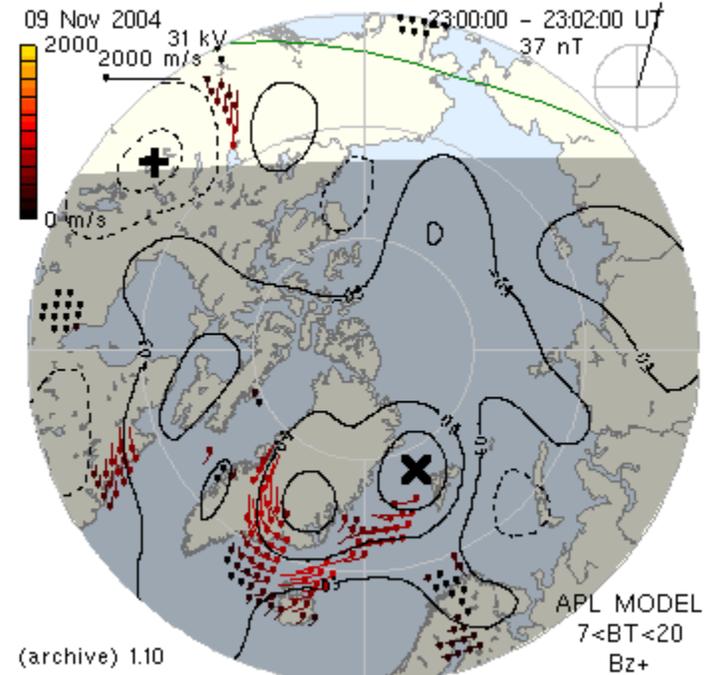

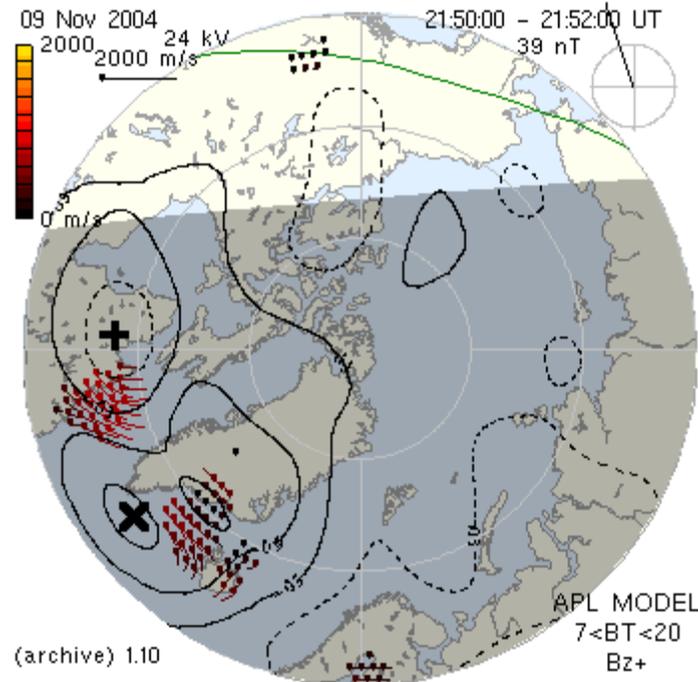

# Geomagnetic Conditions: November, 2004

# Context and Boundaries: GPS TEC, DMSP

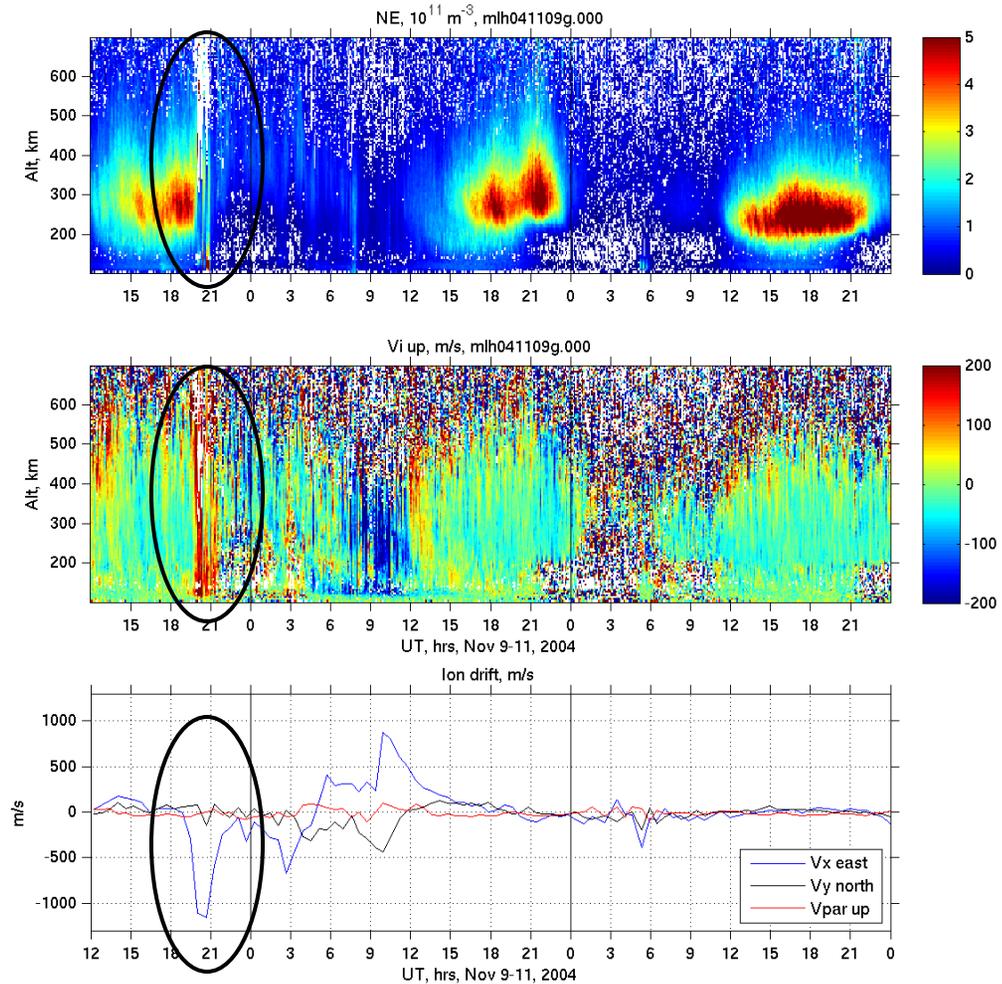

# Millstone Hill , Sondrestrom: Auroral Stations

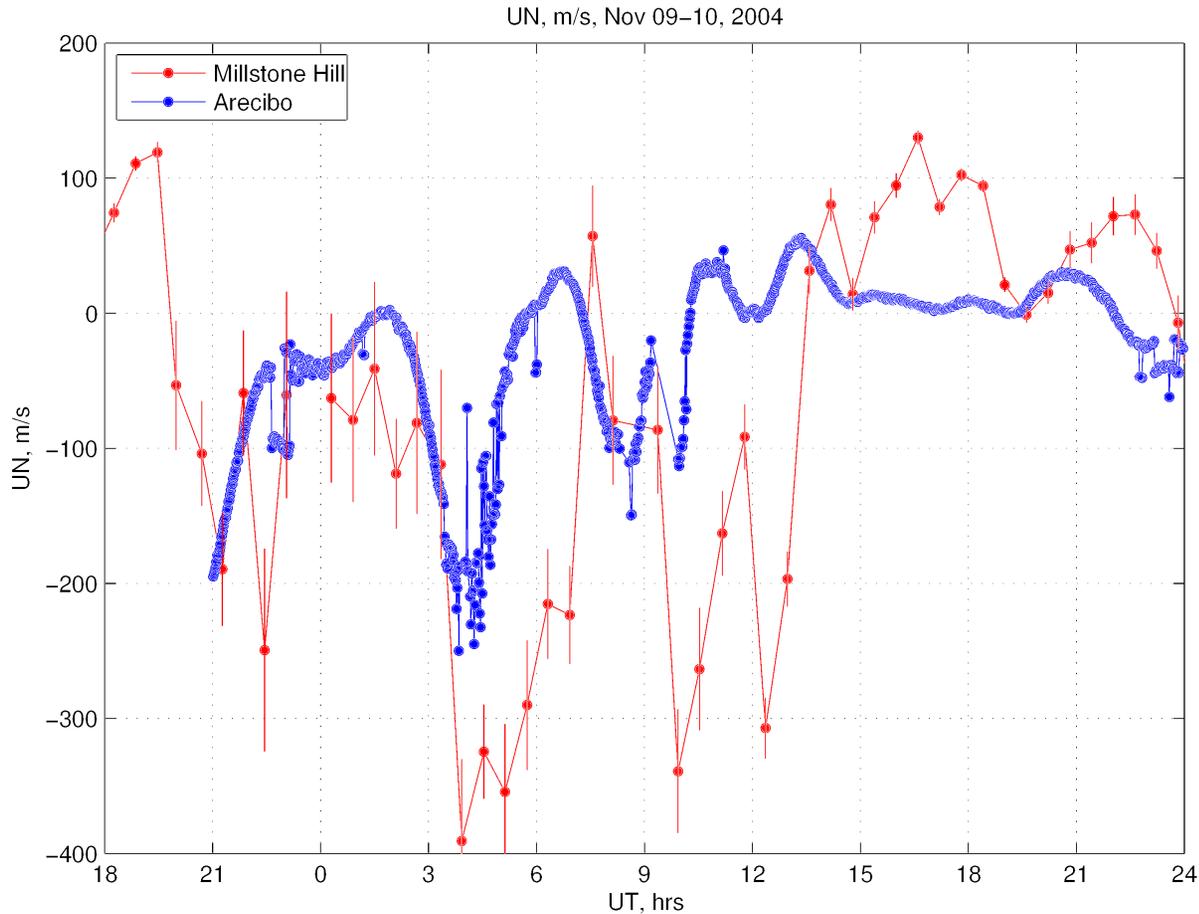

- SuperDARN shows complicated convection pattern
- Millstone Vpe should be compared with Sondrestrom Vpn – both consistent with convection

# Millstone Hill Plasma Parameters: Dusk Sector

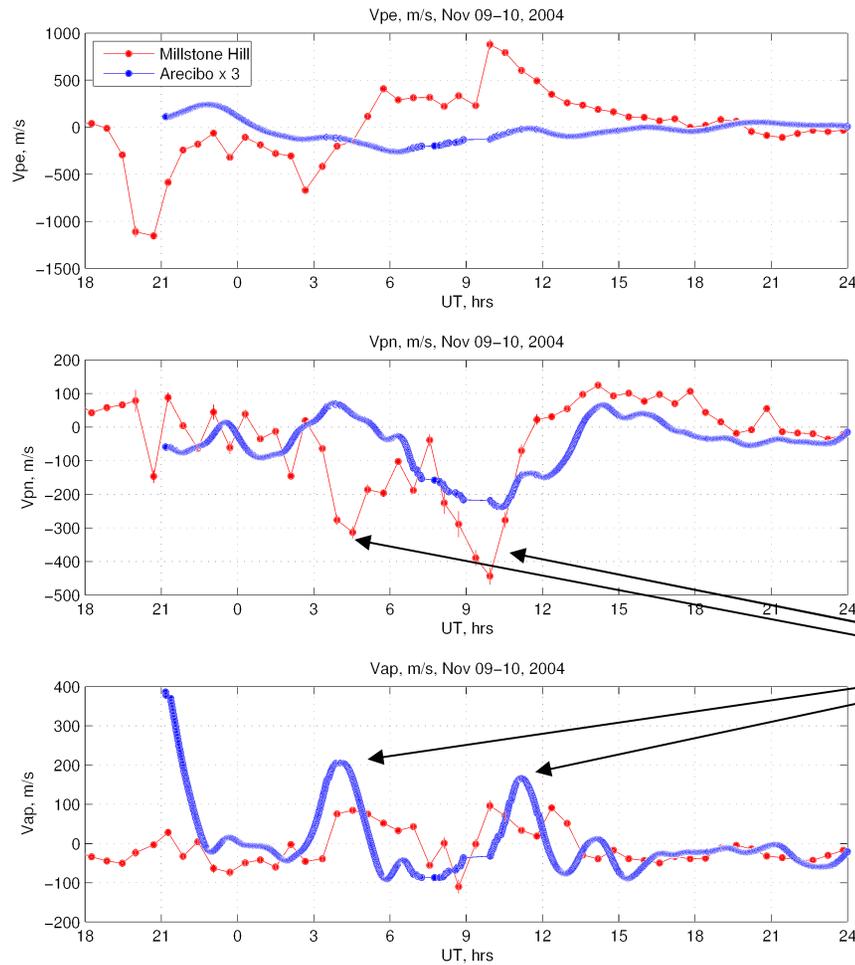

- Initial dusk sector penetration E (19-21 UTC) strongly eastward but not much  $V_{pn}$ ,  $V_{ap}$  seen unlike Arecibo
- Simultaneous strong poleward SAPS E leads to strong westward flow
- American sector declination: westward flow gives upward velocity – major contributor to upwards  $V_i$  @ MHO
- Equatorward wind would also contribute

# Meridional Neutral Wind: Millstone Hill and Arecibo

- Strong equatorial wind surges seen at 21 UTC, 03-04 UTC, 08-09 UTC
- Millstone winds larger than Arecibo
- Chain timing not consistent with propagating TID pole to equator (but consider context)

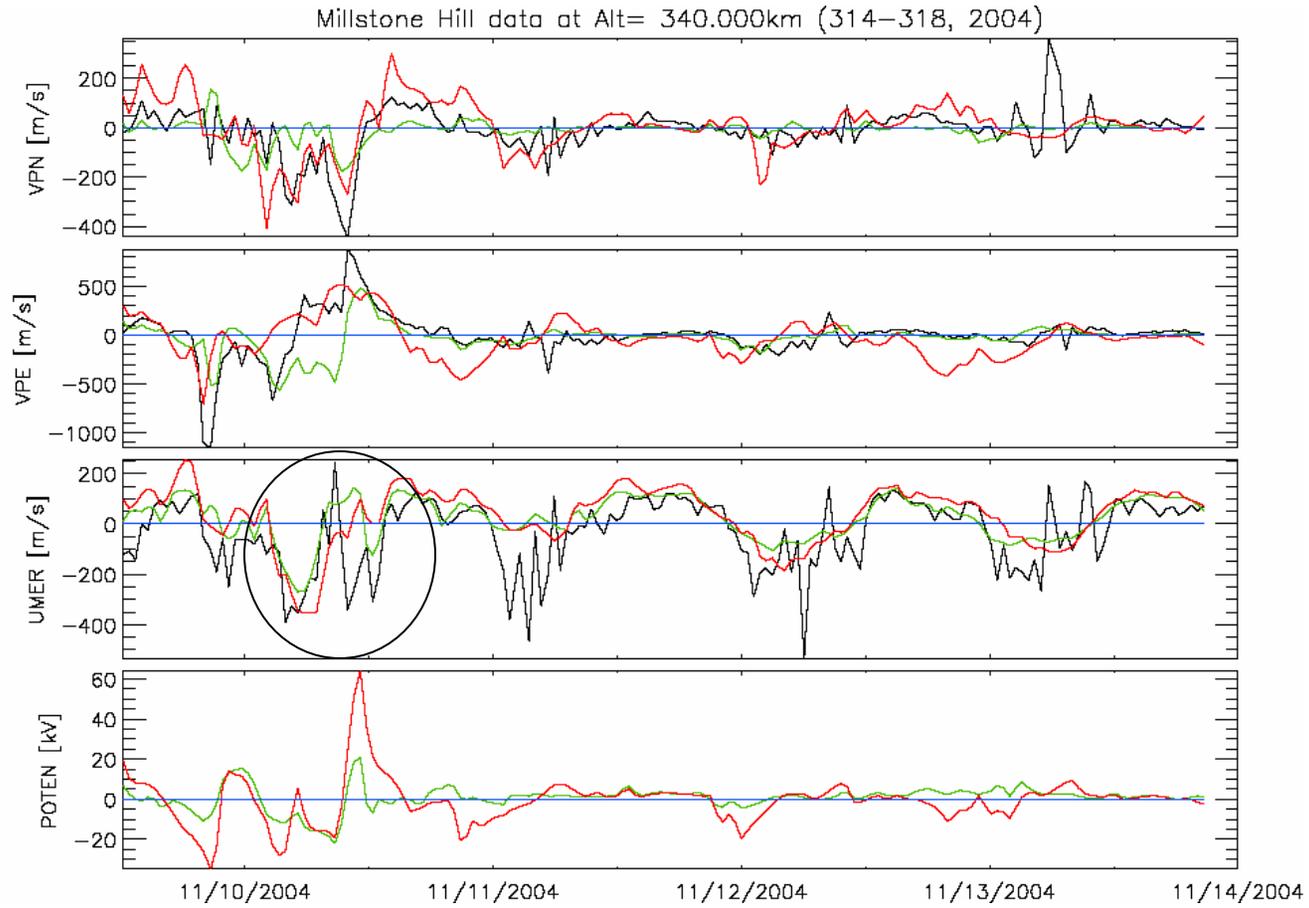

# Millstone Hill, Arecibo Ion Drift Vectors

Ion drifts maximize following wind increases (Dynamo effects)

# TIMEGCM

Millstone Hill Data    TGCM Run # 2 @ 42.6 Lat    TGCM Run # 2 @ 52.6 Lat

# Summary

---

- Very low TEC ( $< 20$  TECU) throughout the night with deep midlatitude trough
- Plasmasphere boundary layer located between MHO and AO at  $\sim 23$  UTC onwards; MHO and Sonde are both auroral radar stations during the night (cf. Apr 14, 1978 event)
- Equatorward neutral wind surges of  $\sim 300$  m/s driven locally by substorms at MHO, AO at 02-04 and 07-09 UTC: dynamo effect creates prompt electric fields and large F layer downdrafts. Substorm timing consistent with Millstone neutral winds (local effects).
- TIMEGCM correctly predicts radar chain effects sometimes (02 UTC) but not other times (07-09 UTC); details of energy inputs are critical
- Detailed model and data investigation of neutral wind surges launched by substorms will follow
